## Hash tables 1

Hash tables with universal hash families guarantee an expected runtime of O(1) for the INSERT, SEARCH, and DELETE operations. What is the meaning of "expected"?

- O It is an average over the choices of the adversary who picks the elements in the table.
- It is an average over the choices of the algorithm who picks the the hash function from the hash family.

Correct

In order to conclude an expected runtime of O(1) for hash table operations, we assumed the following two happen in some specific order:

- The adversary picks elements  $x_1, \ldots, x_n$  for the hash table.
- The algorithm picks a hash function from the hash family.

In what order do these happen?

- Algorithm first, and then adversary.
- Adversary first, and then algorithm.
- O It does not matter.

Correct

Bit lengths

Suppose that there is a toy box with N toys in it. You have a label printer that can print arbitrary strings of 0s and 1s. If you produce labels for the N toys in such a way that each toy gets a unique label, what can be said about the longest label's length?

- $\bigcirc \geq \Omega(\log N)$
- $O \leq O(N)$
- $O \geq \Omega(N)$

Correct

As a remark, for any labeling scheme, the same lower bound of  $\Omega(\log N)$  applies even to the average label length, not just the longest label length.

If you produce labels in a way that minimizes the longest label's length, what is this minimum?  $O \Theta(N)$ 

- $O \Theta(1)$

Correct

If our toy box consists of all functions from  $\{0, \ldots, M-1\}$  to  $\{0, \ldots, n-1\}$ , what is the minimum longest label's length?

- $O \Theta(Mn)$
- $O \Theta(M)$
- $\bigcirc$   $\Theta(M \log n)$
- $O \Theta(n \log M)$

Correct

## 3 Modular arithmetic

Suppose that M > 1000 (the universe size) is a prime number. If we pick  $a \in \{1, ..., M-1\}$  and  $b \in \{0, ..., M-1\}$ , independently and uniformly at random, what is

 $\mathbb{P}_{a,b}[a \times 12 + b = 34 \pmod{M} \text{ and } a \times 56 + b = 78 \pmod{M}]$ ?

- $\bigcirc$   $\frac{1}{M(M-1)}$ O  $\frac{1}{M}$
- O  $\frac{1}{M^2}$
- O 0

 $\mathbb{P}_{a,b}[a \times 12 + b = 34 \pmod{M} \text{ and } a \times 56 + b = 34 \pmod{M}]$ ?

Correct

O  $\frac{1}{M(M-1)}$ 

O  $\frac{1}{M}$ O  $\frac{1}{M^2}$ **O** 0

How about

Correct

In fact for any pair of distinct elements x, y in the universe,  $u = a \times x + b \mod M$  and  $v = a \times y + b$ 

 $\operatorname{mod} M$  are uniformly distributed amongst all distinct pairs. How many elements of  $\{0, ..., M-1\}$  are equal to 0 modulo n?  $\bigcirc$   $\lceil M/n \rceil$ 

- O |M/n|O |M/n| + 1
- In fact, for any i, the number of elements from  $\{0, ..., M-1\}$  equal to i modulo n is  $\leq \lceil M/n \rceil$ .

Let u=0; pick v uniformly at random from  $\{0,\ldots,M-1\}-\{u\}=\{1,\ldots,M-1\}$ . What is the

Correct

O  $\frac{1}{M-1}$ O  $\frac{n}{M-1}$ 

Correct

You can verify that the answer above is always  $\leq 1/n$ . The same answer holds as an upper bound if we changed u from 0 to any other element in  $\{0, \ldots, M-1\}$ .

Hash family size

4

chance that  $v = u \pmod{n}$ ?

Suppose that we have a universe of size M, and our hash table size is n. If  $n \geq M$ , what is the minimum size of a universal hash family?

Suppose now that  $M = n^{100}$  and we have a nonempty hash family H. Let  $h^*$  be one of the hash functions in H. Since M > n,  $h^*$  must map at least two distinct elements  $x^*$ ,  $y^*$  in the universe to the same bucket (by the pigeonhole principle). What can be said about  $\mathbb{P}_{h\sim H}[h(x^*)=h(y^*)]?$ 

Correct

Correct

O = 0 $\bigcirc$   $\geq 1/|H|$  $O \leq 1/n$ 

This means that if H is universal, then

this hash family?  $O \geq \Omega(\log n)$ 

 $1/n \ge \mathbb{P}_{h \sim H}[h(x^*) = h(y^*)] \ge 1/|H|,$ or in other words  $|H| \ge n$ . What can be said about the minimum longest 0/1 label length for labeling

 $O \geq \Omega(\log M)$ Both of the above. Correct

- For the universal hash family from lecture, how many bits do we need to label the hash functions, if we minimize the longest label's length?
- $O \Theta(1)$

 $\Theta(\log n)$ ) when  $M = n^{100}$ .

 $O \Theta(M)$ 

Correct This shows the hash family from lecture can be labeled by the optimal number of bits  $(\Theta(\log M) =$
